

System Testing

System Testing is a type of testing in which the complete and fully integrated software system is tested as a whole. The main purpose of system testing is to check whether the system works correctly after integrating all modules, meets all the specified user requirements, and shows correct end-to-end behavior.

Types of System Testing

1. Recovery Testing

Recovery Testing checks the ability of the system to recover from failures such as system crashes, power failures, hardware faults, or network failures. It ensures the system can restart properly, no important data is lost, and the system returns to normal working condition.

2. Security Testing

Security Testing ensures that the system is protected from unauthorized access, attacks, and data theft. It includes authentication, authorization, data encryption, and vulnerability testing.

3. Stress Testing

Stress Testing checks how the system behaves under extreme load or limited resources. It helps find the breaking point of the system and ensures graceful failure without data loss.

4. Performance Testing

Performance Testing evaluates speed, responsiveness, scalability, and throughput of the system under expected load. It includes load testing, spike testing, and volume testing.
